## Abstract

**Objective:** The objectives of this study was to analyse the anti-inflammatory effects of the *Lactobacillus casei* strain Shirota on epithelial cell expression of Interleukin 8 (IL-8) and human beta-defensin 2 (hBD-2) in the presence of pathogenic bacteria in vitro. **Methods:** HaCaT epithelial-cells ( $1 \times 10^5$  cell/mL) were exposed to heat-killed *Streptococcus mutans* or *Porphyromonas gingivalis* ( $1 \times 10^7$  CFU/mL) and then challenged with the probiotic *L. casei* strain Shirota for 3, 6, and 24 hours. The mRNA transcription levels of IL-8 and hBD-2 were analysed by RT-PCR. Additionally, cell viability was analyzed using MTT (3-[4,5-dimethylthiazol-2-yl]-2,5 diphenyl tetrazolium bromide) assay. Data statistically evaluated by one-way ANOVA test. **Result:** *L. casei* does not effects the HaCaT epithelial cells viability (101.3%). Interleukin 8 and hBD 2 transcription on HaCaT cells were increased after exposed to the heat-killed bacteria. The addition of *L. casei* reduced the transcription levels of IL-8; in contract, probiotics challenges increased the transcriptional expression of hBD 2 mRNA in the HaCaT cells ( $p < 0.05$ ). Interleukin 8 expression significantly reduced ( $p < 0.05$ ) after the *L. casei* challenge. **Conclusion:** *L. casei* conveyed a beneficial immune modulation, reducing IL-8 levels and elevating production of hBD-2. The epithelial cells showed no cytotoxic effects from *L. casei*. Further studies are needed to investigate the molecular processes related to this probiotic's anti-inflammatory properties.

Keywords: cytokine, gene expression, human beta-defensins-2, interleukin-8, *Lactobacillus casei*

## INTRODUCTION

Inflammation in the oral cavity often occurs due to an increase in the normal oral flora, such as *Streptococcus mutans*, a primary pathogenic species that caused dental caries.<sup>[1]</sup> Prolonged accumulation of plaque on the gingival margin and the subgingival region leads to a larger colonization of anaerobic bacteria, such as *Actinomyces* spp., *Porphyromonas gingivalis*, and *Treponema denticola*.<sup>[2,3]</sup> Bacterial colonization around the periodontal tissue causes increased production of interleukin, a cytokine involved in the regulation of immune responses and inflammatory reactions.<sup>[4,5]</sup>

During infections, epithelial cells provide the primary defense against pathogenic invasion, rapidly expressing and up-regulating proinflammatory cytokines, such as interleukin (IL)-8, as part of an instant innate immune response.<sup>[6]</sup> Most epithelial cells, including keratinocytes and human oral epithelial cells<sup>[7]</sup> are rich in IL-8 during inflammation.<sup>[8]</sup> In addition to cytokines, the epithelium also expresses defensins, a small cationic antimicrobial peptides which have a antimicrobial activity against positive and negative Gram bacteria, candida, and viruses.<sup>[9,10]</sup> hBD-2 protein is present in the gingival epithelium, saliva, and cecicular gingival fluid, leading the immune system's defense in the oral cavity.<sup>[11]</sup> The expression of hBD-2 increases during inflammation.<sup>[12]</sup>

Probiotics have an important roles in maintaining immunological function. Probiotics are needed to develop the immune system, protecting the body from disease-causing bacteria. Microflora classified as probiotics are primarily lactic acid-producing bacteria of the genus *Lactobacillus* and *Bifidobacteria*<sup>[5]</sup>. Probiotic bacteria can improve oral health. Consuming probiotic yogurt containing *B. lactis* shown to reduce *Streptococcus mutans* level in the saliva.<sup>[13]</sup> Many studies, have been conducted to assess the probiotics anti-inflammatory properties.

Several *in vitro* studies have used human dendritic cells, intestinal T cells, intestinal porcine epithelial cells (IPEC), monocyte derived dendritic cells, and peripheral-blood mononuclear cells. Chemical inflammation induction of animal models or human patients have also involved in many *in vivo* studies. <sup>[14,15,16]</sup>

Different strains of *Lactobacilli* promote different host cell responses<sup>[17]</sup>, therefore the results from one strain cannot be generalized to others. <sup>[18]</sup> *L. casei* Shirota as probiotic possesses specific biological activity in the human body and has been used widely as yogurt drinks and dairy food in Japan and Europe. <sup>[16]</sup> *L. casei* Shirota is considered safe and it is thought to activate the host's immune systems<sup>[19]</sup> by inducing cytokines such as interferon- $\gamma$ , interleukins, and TNF- $\alpha$ , <sup>[16]</sup> also T-cells and natural killer (NK) cells. <sup>[20]</sup> This study explored how *L. casei* strain Shirota affects HaCaT epithelial cell lines, specifically focusing on the *in vitro* expression of chemical mediators related non-specific and specific immune responses, interleukin 8 and human beta-defensin 2.

## **MATERIALS AND METHODS**

### **Cell lines, bacterial strains, and infections**

Commercial probiotic drinks containing *L. casei* strains Shirota were cultured in de Mann, Rogosa and Sharpe (MRS) agar for 24 hours at 37°C in a medium containing 30 mg glucose. An inoculum comprising 1% of the culture was re-cultured into MRS broth and incubated for 16 hours. For bacterial harvesting, the solution was centrifuged at 4000  $\times$  g and rinsed using 50 mL phosphate buffer saline (PBS) (pH 7.5). *L. casei* was confirmed using PCR.

*S. mutans* ATCC 25175 cultured in brain-heart infusion (BHI) broth and incubated in a CO<sub>2</sub>-enriched atmosphere at 37°C. *P. gingivalis* ATCC 33277 was cultured in BHI broth using the GasPak jar system. Both of them were purchased from DIPA lab. The *L. casei* strain Shirota

( $10^6$  CFU/ml) (isolated above) cultured in MRS broth at 37°C for 48 hours under anaerobic conditions.

HaCaT cells, derived from human epithelial cells, were purchased from Oral biology laboratory, International Islamic University Malaysia. HaCaT cells were cultured in DMEM medium (Gibco, USA) added with 10% (v/v) Fetal Bovine Serum (FBS) (Gibco, USA), 1% Fungizone, 100 uG/mL streptomycin, and 10 uG/mL penicillin. The cells were incubated in tissue culture flasks at 37° C in a humidified atmosphere (RH 96%) with 5% CO<sub>2</sub>. The HaCaT cells were centrifuged (Hermle, USA) at 2000 rpm for 10 minutes at 4°C, suspended in DMEM complete medium, and plated into culture flasks. Cell enumeration was performed with a haemocytometer with two flasks were counted per time point and growth condition.

The confluent culture of HaCaT cells ( $10^5$  cell/mL) (Fig.1) was exposed to heat-killed (by heating to 80°C) *S. mutans* ATCC 25175 ( $10^7$  CFU/mL) or *P. gingivalis* ATCC 33277 ( $1 \times 10^7$  CFU/mL) for 24 hours at 37° C and 5% CO<sub>2</sub>. Subsequently, probiotic *L. casei* strain Shirota ( $10^7$  CFU/mL) were added to the cell cultures, incubated for 3, 6, and 24 hours' time period. After 1 h of infection, cells were washed in PBS and the RNA extraction is carried out.

Figure 1. Confluent HaCaT cell culture seen under an inverted microscope.

#### **Analysis of cell viability using a metabolic assay**

Cells viability were assessed using the metabolic assay based on the reduction of MTT (3-[4,5-dimethylthiazol-2-yl]-2,5 diphenyltetrazolium) by the mitochondrial dehydrogenase of intact cells to form a purple formazan product. HaCaT cells ( $10^5$  cells per well) plated in a 96-well plate and treated with *L. casei* ( $1 \times 10^7$  CFU/mL). After incubations of 15 and 30 minutes, 1 hour, 3 hours, 6 hours, and 24 hours, MTT (1 mg/ml in PBS) (VWR Life Science, USA) was added to the wells, and cells were incubated for three hours. The formazan amount was analysed by measuring the absorbances at 490nm using a microplate-reader (SAFAS, Monaco). The cells viability were measured as a percentage using the formula: cell death (%) = (control cells optical density (OD) – sample cells OD)/control cells OD x 100%. The assay was performed in triplicate.

### **RNA Extraction**

IL-8 and hBD 2 mRNA expression levels were determined by RT-PCR. RNA extraction was performed using TRIzol reagents (Invitrogen/Thermo Fisher Scientific, Waltham, Massachusetts, USA). Approximately, 1 mL of TRIzol was added into the cells, followed by incubation for 5 minutes at room temperature. Then, 200  $\mu$ L of chloroform was added. Next, the suspension was transferred into a new 1.5 mL microtube, and the tube was flipped for 15 seconds to homogenize the mixture. After that, the suspension was incubated for 3 minutes at room temperature, and then was centrifuged at  $12,000 \times g$  for 15 minutes  $4^\circ\text{C}$ . The upper layer (aqueous phase) was taken out, and then transferred into a new 1.5 mL microtube. 100% isopropanol at amount of 0.5 mL was added into the tube, and then incubated at room temperature for 10 minutes. The tube was then centrifuged at  $12,000 \times g$  for 10 minutes at  $4^\circ\text{C}$ . The supernatant was discarded, and 75% ethanol at amount of 1 mL was added into the tube. The mixture was homogenized using a vortex mixer, and then was centrifuged again at  $7,500 \times g$  for 5 minutes at  $4^\circ\text{C}$ . The supernatant was removed, and the pellet was allowed to air-dry for 10 minutes at room temperature. The RNA-containing pellet was then resuspended again by adding 20  $\mu$ L of ddH<sub>2</sub>O, and incubated in a thermoblock machine (Biosan, Riga, Latvia) at  $57^\circ\text{C}$  for 15 minutes. After that, the pellet was stored at  $-70^\circ\text{C}$ . A spectrophotometer was used to determine RNA concentration. The isolated RNA was taken out (approximately 2  $\mu$ L), and

diluted in 498  $\mu\text{L}$  ddH<sub>2</sub>O. Then, RNA solution was fed into a glass cuvette, and the cuvette was inserted to the spectrophotometer. The RNA concentrations were determined using a spectrophotometer (SAFAS, Monaco).

### **Reverse transcription from RNA to cDNA and qPCR**

After the RNA concentration was measured, reverse transcription (RT)-PCR was performed to obtain the cDNA sequences. We used Thermo Fisher Scientific's GeneAmp Gold RNA PCR Reagent Kit with a random oligo (dT) primer and 1  $\mu\text{g}$  of RNA template (Thermo Fisher Scientific, USA). Total reaction (25  $\mu\text{L}$ ) containing 12.5  $\mu\text{L}$  of SYBR-Green PCR MasterMix, forward and reverse primers (300 nM), nuclease-free water (11  $\mu\text{L}$ ), and cDNA sample (1.5  $\mu\text{L}$ ). The initial denaturation step was set for 1 min at 95°C and amplified for 40 cycles (15 second) at 95°C and 60 second at 60°C. All primers used are listed in Table 1 for IL-8<sup>[8]</sup> and hBD-2<sup>[21]</sup>, as well as glyceraldehyde-3-phosphate dehydrogenase (GAPDH) <sup>[8]</sup>. IL-8 and hBD 2 levels were normalized to the GAPDH expression level. qPCR method was performed in triplicate, with an StepOne<sup>TM</sup>. RT-PCR System (Thermo-Fisher Scientific, USA) and the specific PCR products amplification was detected using the SYBRGreen PCR Master Mix (Applied Biosystem, USA). The DNA quantification of each sample was done using the  $2^{-\Delta\Delta\text{Ct}}$  formula, where the Ct value represents the threshold cycle of PCR at which the amplified product was detected. All treatment were performed in triplicate.

Table 1. Primers used for RT-PCR

Primers	Sequence (5'-3')
IL-8 forward primer	TCTCTTGGCAGCCTTCCT
IL-8 reverse primer	ACTGAACCTGACCGTACATGTCTTTATGCACTGACATCT
hBD-2forward primer	GGTGTTTTTGGTGGTATAGGC
hBD-2 reverse primer	AGGGCAAAGACTGGATGACA
GAPDH forward primer	CTGAGTACGTCGTGGAGTC
GAPDH reverse primer	ACTGAACCTGACCGTACACAGAGATGATGACCCTTTTG

### Statistical analysis

The one-way analysis of variance (ANOVA) tests were applied to reveal significant differences in IL-8 and hBD 2 mRNA expressions in HaCaT cells exposed to *S. mutans*, *P. gingivalis* and *L. casei* for a range of treatment times in three independent experiments. The value of  $p < 0.05$  were considered as statistically significant different. The SPSS Statistics for Windows software version 20 (IBM, USA) was used for statistical calculations.

## RESULTS

### MTT assay to assess *L. casei* cytotoxicity on epithelial cells (HaCaT)

*L. casei* cytotoxicity on the HaCaT epithelial cells was assessed using the MTT assay to measure cell viability according to ISO 10993-5. Results showed the HaCat cell viabilities were in the range of 91.8% – 106.7%. Result indicate that *L. casei* does not cause toxicity in human epithelial cells (Fig. 2).

Figure 2. The percentage of viable HaCaT cells after treatment with *L. casei*. HaCaT cells were seeded in a 96-well plate at a density of  $10^4$  cells/well. Cells were treated with  $10^6$  colony-forming units (CFU)/mL of *L. casei* for 15 min, 30 min, 1 h, 3 h, 6 h or 24 h. A 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) determined the percent of cell viability. Each treatment was done in triplicate.

***L. casei* reduced the HaCaT expression levels of IL-8 after incubation with *Streptococcus mutans*- or *Porphyromonas gingivalis***

IL-8 mRNA expression levels were obtained during the initial incubation of the HaCaT cells with the heat-killed bacteria and during the cells' subsequent incubation with *L. casei* for 3 hours, 6 hours, and 24 hours. IL-8 expression levels increased significantly after exposing the cells to *S. mutans* ( $P = 0.000$ ) or *P. gingivalis* ( $P = 0.000$ ) [Figure 3a and b]. The addition of *L. casei* could inhibit both *S. mutans* and *P. gingivalis* IL-8 mRNA expression of HaCaT cells at 3 h, 6 h and 24 h of treatment ( $P = 0.000$ ). Significant differences were observed when *S. mutans*-induced IL-8 mRNA expressions in *L. casei* for 3 h and 24 h ( $P = 0.000$ ) were

compared. Significant differences were also observed when *P. gingivalis*-induced IL-8 mRNA expressions in *L. casei* for 3 h and 24 h ( $P = 0.000$ ) [Figure 3a and b] were compared.

Figure 3. Interleukin-8 (IL-8) mRNA expression of HaCaT cells exposed to heat-killed *Streptococcus mutans* (a) or *Porphyromonas gingivalis* (b) and treated with *Lactobacillus casei*. One hundred thousand HaCaT cells were exposed to  $10^7$  colony-forming units (CFU) of

preheated *S. mutans* or *P. gingivalis* for 24 hours and then treated with  $10^7$  CFU of *L. casei* for 3, 6, or 24 hours. Each treatment was done in triplicate.

***L. casei* increased the HaCaT expression levels of hBD-2 after incubation with *Streptococcus mutans*- or *Porphyromonas gingivalis***

hBD-2 expression levels increased after exposing the cells to *S. mutans* or *P. gingivalis* [Figure 4a and b]. In contrast to IL-8, the hBD 2 mRNA expression increased significantly in HaCaT cells exposed to *S. mutans*, *P. gingivalis* after *L. casei* treatment in three and six hours period ( $P = 0.000$ ). The hBD-2 mRNA expressions in the HaCat cells exposed to *S. mutans* or *P. gingivalis* and *L. casei* were significantly decreased after 24 h of treatment ( $P = 0.000$ ) [Figure 4a and b].

Figure 4. Human Beta Defensin-2 (hBD-2) mRNA expression of HaCaT cells exposed to heat-killed *Streptococcus mutans* (a) or *Porphyromonas gingivalis* (b) and treated with *L. casei*. One hundred thousand HaCaT cells were exposed to  $10^7$  colony-forming units (CFU) of preheated *S. mutans* or *P. gingivalis* for 24 hours and then treated with  $10^7$  CFU of *L. casei* for 3, 6, or 24 hours. Each treatment was done in triplicate.

## DISCUSSION

Host cell immune responses can vary depending on the type of invading pathogen. In this study, heat-killed bacteria were used to avoid bacterial overgrowth in the medium and the overproduction of immune responses in the cultured cells. The heat-killed Gram-positive *S. mutans* and Gram-negative *P. gingivalis* both successfully induced the expression of interleukin 8 and human beta-defensin 2 in vitro during the initial incubation period. We also noticed a slight increase in IL-8 and hBD 2 mRNA expression immediately after *L. casei* was added to the cells. This was likely due to the presence of lipoteichoic acid in the *L. casei* cell wall. The cell walls of *Lactobacilli* and other Gram-positive bacteria contain peptidoglycans and lipoteichoic acid.<sup>[22]</sup> These components can modulate the pro-inflammatory cytokines production such as interleukin 8 through the signaling pathways activation, primarily through transcriptional nuclear factor (NF)-kB, the phosphatidylinositol-3-kinase-Akt (PI3K/Akt) pathway<sup>[23]</sup>, the mitogen-activated protein kinase (MAPK) pathway, and Toll-like receptors (TLRs).<sup>[24,25]</sup>

Most epithelial cells produce cytokines in response to inflammation. IL-8 is the most predominant cytokine found in keratinocytes. Although IL-8 is required to eliminate invading pathogens from inflammation sites, prolonged IL-8 expression is considered dangerous to the host cells because it can lead to cell apoptosis and tissue destruction due to massive neutrophil infiltration.<sup>[23]</sup> Thus, host cell interleukin-8 production is both dose and time dependent.<sup>[26]</sup> *Lactobacilli* strains has been proved to suppressed the production of interleukin-8 in bacteria-derived lipopolysaccharides stimulated intestinal epithelial cells.<sup>[27]</sup> *L. casei* modulates interleukin 8 expression by inhibiting NF-kB activation at a terminal step in the signalling pathway.<sup>[28]</sup>

A study of cultured epithelial cells, which were infected with *Shigella flexneri* and then challenged with *L. casei*. *L. casei* downregulated the transcription of cytokines, chemokines, and adherence molecules as pro-inflammatory factors. This anti-inflammatory effect appeared to be mediated by inhibition of the NF- $\kappa$ B pathway, particularly through stabilization of I- $\kappa$ B $\alpha$ .<sup>[28]</sup> Study concerning the ability of *Lactobacillus* to suppress the production of pro-inflammatory cytokine from colonic epithelial cells that has been stimulated by *C. difficile*, *L. casei* L39 isolate, along with another two *Lactobacillus rhamnosus* isolates (*L. rhamnosus* L35 and *L. rhamnosus* L34) have significantly suppressed approximately 50% of interleukin-8 production compared to the control through inactivation of transcription factors without inhibiting toxin production or *C. difficile* growth.<sup>[29]</sup> Another study showed that *Lactobacillus reuteri* with glycerol supplementation significantly reduced the expression of IL-8 on infected epithelial cells.<sup>[30]</sup>

In this study, the transcription levels of hBD-2 were increased after exposed to *S. mutans* or *P. gingivalis* and *L. casei*. This result is in concordance with the previous study of Niyonsaba *et al.*, which reported that epithelial tissues contain high amounts of hBDs at the sites of inflammation, although the average concentrations were not precisely known.<sup>[31]</sup> Another study showed increasing levels of beta defensin-2 expression in the epithelial parotid glands after the addition of *L. reuteri*.<sup>[32]</sup> Expression of hBD-2 can be induced by various pro-inflammatory agents, including TNF- $\alpha$ , Gram-negative bacterial lipopolysaccharides, Gram-positive bacteria, and yeast infections.<sup>[26,33]</sup> In our study, the increase of hBD-2 expression peaked in the first stages (at 3 and 6 hours) after the introduction of the heat-killed bacteria. According to Yoon *et al.*, in a study using intestinal epithelial cells, increased hBD-2 mRNA expression was first noted two hours after stimulation and peaked at six hours post stimulation

before decreasing to the baseline. This data reveals the time-dependent manner of epithelial cell hBD-2 expression. [34]

The expression of hBD-2 in epithelial cell is primarily regulated by signaling pathways through TLRs, [26] MAPK, NF-kB, or activator protein (AP)-1. [34,35,36] The hBD-2 gene contains promoter with binding sites for NF-kB and AP-1. [34,37] Lactic acid bacteria are known to induce hBD expression in host cells through the transcription factors NF-kB and AP-1. [38]

Reports have also indicated that hBDs can encourage wound healing by defensin-stimulated cell-proliferation and increased wound closure *in vitro*, thus benefiting tissue regeneration. [39,40] Similarly, preliminary studies have examined the wound-healing effects of the *L. casei* strain Shirota used in probiotic drinks. Results from animal experiments have shown that *L. casei* may help heal oral cavity ulcers and speed up epithelization. [41] These properties would be useful for periodontal treatments [42] and post extraction management. [43] Interest in probiotic research has grown in recent decades; however, little information about the use of probiotic bacteria in the oral cavity has been reported. The anti-cancer, anti-inflammatory, and anti-fungal properties of probiotics as well as their immune-boosting benefits are beyond doubt. [38,44]

## **CONCLUSION**

This study indicated that the *L. casei* strain Shirota does not possess cytotoxicity against HaCaT epithelial cells. *L. casei* conveyed a beneficial immune modulation, reducing IL-8 levels and elevating production of hBD-2. Further studies are encouraged to investigate this probiotic's anti-inflammatory properties at the molecular level.

## **Acknowledgement**

Author thanks to Dr. Solachuddin Jauhari Arief from Faculty of Dentistry, University of International Islamic Malaysia for kindly providing HaCat cell lines.
